# MPMS Service Note 1090-310

# **Testing for RSO Transport-SQUID Signal Coupling**

This service note describes simple procedures for troubleshooting sources of an increase in the RSO noise floor. It is meant as a starting point to help you rule out some basic causes of a noise floor increase. Three types of symptoms are addressed: an otherwise good data set with numerous bad data points that cannot be attributed to normal magnet issues (e.g., flux jumps and large SQUID drifts); an apparent loss of reasonable SQUID tuning parameters or fluctuations in them; and a general increase in the RSO noise floor to the region of 10<sup>-5</sup> emu instead of the expected 10<sup>-8</sup> emu.

The Reciprocating Sample Option (RSO) is meant to increase the ultimate sensitivity achievable with the MPMS SQUID based magnetometer. However, with the RSO transport installed, you might appear to get better data with the traditional DC stepped-scan technique than you do with the synchronous RSO technique. The likely cause of this situation is coupling between the RSO transport cable and the SQUID detection system.

Coupling and increased noise levels commonly develop after you have changed from the preferred RSO transport to the standard transport so that you could use a specialty probe (e.g., resistivity, fiber optic). When the RSO transport is re-installed, changes in the position of the cables can cause an increase in coupling.

The following set of procedures will help you isolate and eliminate any such coupling. To summarize, you will prepare the system for the procedures, perform a standard SQUID drift test, check for coupling between the transport and SQUID voltage by manually moving the transport, and finally, verify the quality of the cables.

# I. Prepare the System for Testing

- 1. Verify that the level of helium in the dewar is at least 50%. If it is not, add helium.
- 2. In the respective text boxes in the **Magnetic Field** dialog box, set the **Field** to 0 (zero), set the **Approach** to **Oscillate**, and set the mode to **High Resolution**.
- 3. Set the temperature to a value between 101 K and 300 K and wait for it to stabilize.
- 4. Prepare the sample chamber and transport for testing:
  - a. Remove the sample rod from the instrument.
  - b. Purge the sample chamber.
  - c. Initialize the transport.

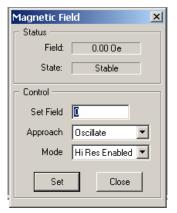

Figure 1. Magnetic Field dialog box

- 5. Reset the system electronics and communications by using the sequence below:
  - a. Exit MultiVu.
  - b. Turn off the power to the computer.
  - c. Turn off the power to the 1822 (top left switch on MPMS XL cabinet).
  - d. Wait 5 seconds.
  - e. Return power to the system using the reverse sequence (turn on the power to the 1822, turn on the power to the computer, and start MultiVu).
- 6. Reset the temperature to a level near its current value (**Instrument >> Temperature**) and wait until it has stabilized.
- 7. Perform an automatic SQUID tuning procedure.
  - a. Open the SQUID Tuning dialog box shown in Figure 2 (Instrument >> SQUID Tune).
  - b. If necessary, select the appropriate tab (Longitudinal or Transverse).
  - c. Click in the check box for Automatic Tuning (middle section of the dialog).
  - d. Click on the Start button.
  - e. When the procedure ends, if the maximum tune value is less than 0.6, please refer to the MPMS user's manual for more details on SQUID-tuning procedures.

SQUID Tuning	×

# II. Perform a Standard SQUID Drift Test

Use the following procedure once the system is at zero (0) field and a stable temperature.

#### II.A Set Data-Logging Parameters

- 1. Open the Log Data dialog (select Utilities >> Log MPMS Data).
- 2. Click on the **Standard Items** tab (Figure 3) to bring it forward.
  - Click on the Select All button to log data for all the items.
  - In the text box under the first column on the left, click on the dropdown arrow and specify the appropriate voltmeter channel (Longitudinal or Transverse) to register the SQUID voltage.

Log Data			_ 🗆 X
General Standard Items

Figure 4. General tab in Log Data dialog

- 3. Click on the **General** tab to bring it forward (Figure 4).
  - In the **General** tab, select an interval of 1.0 seconds and use the **Browse** button to create a file (e.g., RSOtest.env).
  - Click on the Start button to start collecting data.
  - Open the plot window by clicking on the **View Data** button in the lower left of the **General** tab.
- 4. After the plot window has opened, use the **Graph: Data Selection** dialog box (right-click on the graph or select **Graph >> Data Selection**) to set the Y1 coordinate to **SQUID** voltage and the X coordinate to **Time**, as shown in Figure 5.
- 5. Click on the **OK** button and leave the **Log Data** utility on for the rest of the procedures.

### II.B. SQUID Drift Test

Perform a SQUID Drift test by using the **SQUID Diagnostics** dialog box shown in Figure 6 (**Utilities >> Diagnostics >> SQUID**).

SQUID Diagnostics
Longitudinal Transverse Status Turning on SQUID heaters. Controls EMU Range @ Normal @ Normal @ Status Turning on SQUID coils @ Auto Reset SQUID s
Range     x1     X1     Set     RF Power     0     Set       Gain     x10     Set     Tuning level     0     Set       Filter     None     Set
Reset Release Hold Momentary Close

Figure 6. Longitudinal tab of SQUID Diagnostics dialog

- 1. If necessary, select the appropriate tab (Longitudinal or Transverse)
- 2. Select the Controls: Emu Range settings:
  - Click in the check box for Normal.
  - Using the dropdown menu, select 0.000125 scale, then click on the **Set** button right next to the text box. (Do not select the check box for **Auto Reset the SQUID while logging output**).
- 3. Click on the Quench SQUID Coils button and wait 5 seconds.
- Examine the plot of the environmental file: If the SQUID voltage is not within the +/- 10 V
  range of the voltmeter card, perform a momentary reset by clicking on the Momentary
  button in the Reset subsection.
- If the SQUID voltage is not in the +/- 10 V range of the voltmeter card after the reset, steadily increase the value of EMU Range until the SQUID voltage reading is in the +/- 10 V range.

You are now performing a standard SQUID drift test. If the voltage drifts out of the +/– 10 V range during the test, perform a momentary reset as in Step 5 above. (Normally, the **Auto Reset the SQUID while logging output** check box would be checked and the software would automatically reset, but we deactivated this option for the test.)

A relatively large SQUID drift is to be expected after a recent large change in the magnetic field. There are two ways to minimize the influence of the vortex motion in the magnet:

- Send a heat pulse through the magnet (Utilities >> Reset Magnet) if your model of MPMS has this option.
- For MPMS models without the Magnet Reset capability, the solution is to leave the magnet at 0 (zero) field for a time—drift should decrease with time (up to one hour) at 0 (zero) field. Contact Customer Service at Quantum Design if the problem has not been resolved after one hour.

If you are seeing sporadic, nonlinear changes in the SQUID voltage, consider environmental sources that might be coupling to the SQUID, especially if your system is not shielded. To determine other factors that can affect the noise levels, please refer to the MPMS user's manual.

# III. Test for Transport–SQUID Voltage Coupling

Watch the SQUID voltage readings while you test for coupling between the SQUID voltage and movement of the transport.

- 1. Open the **Transport Diagnostics** dialog box shown in Figure 7 (**Utilities >> Diagnostics** >> **Transport**).
- 2. Move the transport by using the **Control** area **Move To** text box:
  - Enter a value of 2 in the text box and click on the **Set** button.
  - Enter a value of 4 in the text box and click on the **Set** button.
  - Enter a value of 6 in the text box and click on the **Set** button.
- 3. Click on the Initialize button.

Under normal circumstances, you should see no change in the SQUID voltage when the transport is moved. But if there is significant coupling, the SQUID voltage will register a value of either +10 V

Transport Diagnostics

Close

or -10 V while the transport is moving, but it will then revert to a stable drift once the transport has stopped moving. Any correlation between transport motion and the SQUID detection system will limit the sensitivity that the RSO method can achieve.

If you observe a correlation, adjust the relative position and routing of the yellow Lemo RSO transport cable with respect to all the other cables in the system. In particular, undo any cable bundles and route the yellow Lemo through its own hole in the back of the electronics cabinet.

After you have adjusted the cables, retest for SQUID–transport coupling by performing Steps 2 and 3 (Procedure III) until there is no discernable change in the SQUID voltage. If performance does not improve after you have adjusted the cable placement, follow the procedures in Section IV, "Cable Quality."

# Automatic Sequence

You can use a sequence such as that shown in Figure 8 to automate the RSO transport– SQUID coupling test. Note that this sequence will fail if there is a large SQUID drift present. Once the sequence has been completed, examine the log file for signs of coupling.

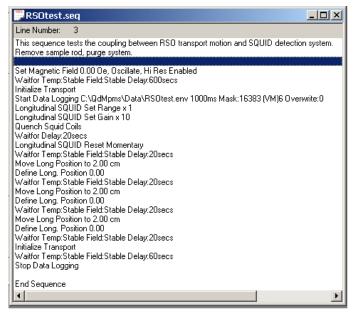

Figure 8. Sequence for automatically testing for RSO transport-SQUID detector coupling.

#### IV. Cable Quality

Examine the quality of the terminal connectors for all the wires involved in the SQUID detection system. Be careful not to apply so much force that you damage the connectors during the testing process.

- 1. Begin a standard SQUID drift test (Section II.B), creating a .env file with a clearly recognizable name like Testcable.env.
- 2. Display the plot of SQUID voltage versus time.
- Move the yellow triax cables that lead from the sidecar on the probe to the RF SQUID amplifier box. The SQUID output voltage is expected to show some variation when these cables are moved, but if the SQUID voltage records the maximum +10 V or −10 V, then the following corrective action is required.
- 4. The following procedures should only be performed by a qualified Quantum Design service representative.
  - a. Place the system in Standby mode (Instrument >> Standby).
  - b. Disconnect the grey multiplexed cable from the RF SQUID amplifier located on the back of the probe cabinet.
  - c. Disconnect the yellow triax cables.
  - d. Tighten by hand the connections at the end of the yellow cables.
  - e. Reconnect the yellow cables and then the grey multiplexed cable.
  - f. Exit Standby mode by clicking on the OK button in the Standby dialog box.
  - g. Retest the quality of the connectors using Steps 1–3.

These cables can, in theory, be damaged by stress applied in routing. They also can be damaged by exposure to low temperatures if the top of the probe and top of dewar get very cold during helium transfers, especially transfers into a warm dewar.

If the above procedures do not help resolve the RSO noise floor increase, the quality of the grounding connection inside the electronics cabinet might be at issue. Please contact Customer Service at Quantum Design for advice before you proceed further. For service centers located inside and outside the USA, go to the Quantum Design website (<u>www.qdusa.com</u>) and select <u>Contact Us</u>.
